## Primary-Side-Regulation PWM Controller for LED Illumination

### Features

- Low Standby Power: < 30 mW
- High-Voltage Startup
- Few External Component Counts
- Constant-Voltage (CV) and Constant-Current (CC) Control without Secondary-Feedback Circuitry
- Green-Mode: Linearly-Decreasing PWM Frequency with Cycle skipping.
- Fixed PWM Frequency at 50 kHz and 33 kHz with Proprietary Frequency Hopping to Solve EMI Problems
- Peak-Current-Mode Control in CV Mode
- Cycle-by-Cycle Current Limiting
- V<sub>DD</sub> Over-Voltage Protection (OVP)
- V<sub>DD</sub> Under-Voltage Lockout (UVLO)
- Adjustable Brownout Detector
- Gate Output Maximum Voltage Clamped at 15 V
- Thermal Shutdown (TSD) Protection
- Available in the 8-Lead SOIC Package

### Description

This third-generation Primary-Side-Regulation (PSR) and highly integrated PWM controller provides features to enhance the performance of LED illumination.

The proprietary topology, TRUECURRENT<sup>®</sup>, enables precise CC regulation and simplified circuit for LED illumination applications. The result is lower-cost and smaller LED lighting compared to a conventional design or a linear transformer.

To minimize standby power consumption, the proprietary green-mode function provides off-time modulation to linearly decrease PWM frequency with cycle skipping under light-load conditions. Green mode assists the power supply in meeting the power conservation requirements.

By using the FL663, LED illumination can be implemented with few external components and minimized cost.

## Pin Definitions

Pin #	Name	Description
1	CS	<b>Current Sense.</b> This pin connects a current-sense resistor to detect the MOSFET current for peak-current-mode control in CV Mode and provides the output-current regulation in CC Mode.
2	GATE	<b>PWM Signal Output.</b> This pin uses the internal totem-pole output driver to drive the power MOSFET. It is internally clamped below 15 V.
3	V <sub>DD</sub>	<b>Power Supply.</b> IC operating current and MOSFET driving current are supplied using this pin. This pin is connected to an external V <sub>DD</sub> capacitor of typically 10 μF. The threshold voltages for startup and turn-off are 16 V and 7.5 V, respectively. The operating current is lower than 5 mA.
4	NC	<b>No Connect.</b> This pin is connected to GND or no connection. Does not connect any voltage source.
5	VS	<b>Voltage Sense.</b> This pin detects the output voltage information and discharge time based on voltage of auxiliary winding.
6	GND	<b>Ground</b>
7	NC	<b>No Connect</b>
8	HV	<b>High Voltage.</b> This pin connects to DC link capacitor for high-voltage startup. This pin is connected to an external startup resistor of typically 100 kΩ.

## Absolute Maximum Ratings

Stresses exceeding the absolute maximum ratings may damage the device. The device may not function or be operable above the recommended operating conditions and stressing the parts to these levels is not recommended. In addition, extended exposure to stresses above the recommended operating conditions may affect device reliability. The absolute maximum ratings are stress ratings only.

## Functional Description

**Figure 19. Basic Circuit of a PSR Flyback Converter for LED Illumination**

Figure 19 shows the basic circuit diagram of a primary-side regulated flyback converter with typical waveforms shown in Figure 20. Generally, Discontinuous Conduction Mode (DCM) operation is preferred for primary-side regulation since it allows better output regulation.

The operation principles of DCM flyback converter are as follows:

### Stage I

During the MOSFET on time ( $t_{ON}$ ), input voltage ( $V_{DC}$ ) is applied across the primary-side inductor ( $L_m$ ). Then MOSFET current ( $I_{DS}$ ) increases linearly from zero to the peak value ( $I_{PK}$ ). During this time, the energy is drawn from the input and stored in the inductor.

### Stage II

When the MOSFET (Q1) is turned off, the energy stored in the inductor forces the rectifier diode ( $D_F$ ) to be turned on. While the diode is conducting, the output voltage ( $V_O$ ), together with diode forward-voltage drop ( $V_F$ ), is applied across the secondary-side inductor and the diode current ( $I_F$ ) decreases linearly from the peak value ( $I_{PK} \times N_P/N_S$ ) to zero. At the end of inductor current discharge time ( $t_{DIS}$ ), all the energy stored in the inductor has been delivered to the output.

### Stage III

When the diode current reaches zero, the transformer auxiliary winding voltage ( $V_A$ ) begins to oscillate by the resonance between the primary-side inductor ( $L_m$ ) and the effective capacitor loaded across MOSFET (Q1).

**Figure 20. Waveforms of DCM Flyback Converter**

### Constant Voltage Regulation

During the inductor current discharge time ( $t_{DIS}$ ), the sum of output voltage ( $V_O$ ) and diode forward-voltage drop ( $V_F$ ) is reflected to the auxiliary winding side as  $(V_O + V_F) \times N_A/N_S$ . Since the diode forward-voltage drop ( $V_F$ ) decreases as current decreases, the auxiliary winding voltage ( $V_A$ ) reflects the output voltage ( $V_O$ ) at the end of diode conduction time ( $t_{DIS}$ ), where the diode current ( $I_F$ ) diminishes to zero. By sampling the winding voltage at the end of the diode conduction time ( $t_{DIS}$ ), the output voltage ( $V_O$ ) information can be obtained. The internal error amplifier for output voltage regulation ( $EAV$ ) compares the sampled voltage with an internal precise reference to generate error voltage ( $V_{COMV}$ ), which determines the duty cycle of the MOSFET ( $Q1$ ) in Constant Voltage Mode.

### Constant Current Regulation

The output current ( $I_O$ ) can be estimated using the peak drain current ( $I_{PK}$ ) and inductor current discharge time ( $t_{DIS}$ ) since output current ( $I_O$ ) is same as the average of the diode current ( $I_{F\_AVG}$ ) in steady state. The output current estimator ( $I_O$  Estimator) determines the peak value of the drain current with a peak detection circuit and calculates the output current ( $I_O$ ) using the inductor discharge time ( $t_{DIS}$ ) and switching period ( $t_s$ ). This output information is compared with an internal precise reference to generate error voltage ( $V_{COMI}$ ), which determines the duty cycle of the MOSFET ( $Q1$ ) in Constant Current Mode. With Fairchild's innovative technique TRUECURRENT<sup>®</sup>, constant current output can be precisely controlled.

### Voltage and Current Error Amplifier

Of the two error voltages,  $V_{COMV}$  and  $V_{COMI}$ , the small one determines the duty cycle. Therefore, during Constant Voltage Regulation Mode,  $V_{COMV}$  determines the duty cycle while  $V_{COMI}$  is saturated to HIGH. During Constant Current Regulation Mode,  $V_{COMI}$  determines the duty cycle while  $V_{COMV}$  is saturated to HIGH.

### Operating Current

The operating current is typically 3.2 mA. The small operating current results in higher efficiency and reduces the  $V_{DD}$  capacitor ( $C_{VDD}$ ) requirement. Once FL663 enters Green Mode, the operating current is reduced to 0.95 mA, assisting the power supply in meeting power conservation requirements.

### Green Mode Operation

The FL663 uses voltage regulation error amplifier output ( $V_{COMV}$ ) as an indicator of the output load and modulates the PWM frequency, as shown in Figure 21. The switching frequency decreases with cycle skipping as load decreases. In heavy load conditions, the switching frequency is fixed at 50 kHz. Once  $V_{COMV}$  decreases below 2.5 V, the PWM frequency linearly decreases from 50 kHz. Once  $V_{COMV}$  decreases below  $V_N$ , the PWM frequency linearly decreases with cycle skipping from 50 kHz to reduce switching losses.

Figure 21. Switching Frequency as Output Load

### Frequency Hopping

EMI reduction is accomplished by frequency hopping, which spreads the energy over a wider frequency range than the bandwidth measured by the EMI test equipment. FL663 has an internal frequency hopping circuit that changes the switching frequency between 47 kHz and 53 kHz.

### High-Voltage Startup

0 shows the startup block. The HV pin is connected to the line input or DC link capacitor ( $C_{DC}$ ). During startup, the internal startup circuit is enabled. Meanwhile, line input supplies the current ( $I_{Start}$ ) to charge the  $V_{DD}$  capacitor ( $C_{VDD}$ ). When the  $V_{DD}$  voltage reaches  $V_{DD-ON}$  (16 V) and  $V_{DC}$  is enough high to avoid brownout, the internal startup circuit is disabled, blocking  $I_{Start}$  from flowing into the HV pin. Once the IC turns on,  $C_{VDD}$  is the only energy source to supply the IC consumption current before the PWM starts to switch. Thus,  $C_{VDD}$  must be large enough to prevent  $V_{DD-OFF}$  (7.5 V) before the power can be delivered from the auxiliary winding. To avoid the surge from input source, the  $R_{Start}$  is connected between  $C_{DC}$  and HV, with a recommended value of 100 k $\Omega$ .

Figure 22. Startup Block

### Protections

The FL663 has several self-protection functions; over-voltage protection, thermal shutdown protection, brownout protection, and pulse-by-pulse current limit.

**V<sub>DD</sub> Under-Voltage Lockout (UVLO)**

The turn-on and turn-off thresholds are fixed internally at 16 V and 7.5 V, respectively. During startup, the V<sub>DD</sub> capacitor (C<sub>VDD</sub>) must be charged to 16 V. The V<sub>DD</sub> capacitor (C<sub>VDD</sub>) continues to supply V<sub>DD</sub> until power can be delivered from the auxiliary winding of the main transformer. V<sub>DD</sub> is not allowed to drop below 7.5 V during this startup process. This UVLO hysteresis window ensures that V<sub>DD</sub> capacitor (C<sub>VDD</sub>) properly supplies V<sub>DD</sub> during startup.

**V<sub>DD</sub> Over-Voltage Protection (OVP)**

The OVP prevents damage from over-voltage conditions. If the V<sub>DD</sub> voltage exceeds 28 V at open-loop feedback condition, the OVP is triggered and the PWM switching is disabled. The OVP has a debounce time (typically 200 μs) to prevent false triggering due to switching noises.

**Thermal Shutdown Protection (TSD)**

The built-in temperature-sensing circuit shuts down PWM output if the junction temperature exceeds 140°C. There is a hysteresis of 15°C.

**Pulse-by-Pulse Current Limit**

When the current sensing voltage (V<sub>CS</sub>) across the current-sense resistor (R<sub>Sense</sub>) of MOSFET (Q1) exceeds the internal threshold of 0.8 V, the MOSFET (Q1) is turned off for the remainder of switching cycle. In normal operation, the pulse-by-pulse current limit is not triggered because the peak current is limited by the control loop.

**Leading-Edge Blanking (LEB)**

Each time the power MOSFET (Q1) switches on, a turn-on spike occurs at the sense resistor (R<sub>Sense</sub>). To avoid premature termination of the switching pulse, a leading-edge blanking time is built in. Conventional RC filtering can be omitted. During this blanking period, the current-limit comparator is disabled and cannot switch off the gate driver.

**Gate Output**

The FL663 output stage is a fast totem-pole gate driver. Cross conduction has been avoided to minimize heat dissipation, increase efficiency, and enhance reliability. The output driver is clamped by an internal 15 V Zener diode to protect power MOSFET transistors against undesired over-voltage gate signals.

**Built-in Slope Compensation**

The sensed voltage across the current-sense resistor is used for Current Mode control and pulse-by-pulse current limiting. Built-in slope compensation improves stability and prevents sub-harmonic oscillations due to peak-current mode control. The FL663 has a synchronized, positive-slope ramp built-in at each switching cycle.

**Noise Immunity**

Noise from the current sense or the control signal can cause significant pulse-width jitter, particularly in Continuous-Conduction Mode. While slope compensation helps alleviate these problems, further precautions should still be taken. Good placement and layout practices should be followed. Avoiding long PCB traces and component leads, locating compensation and filter components near the FL663, and increasing the power MOSFET gate resistance are advised.

**Operation Area**

Figure 23 shows operation area. FL663 has two switching frequency (f<sub>s</sub>) in Constant Current Mode. One is 50 kHz. In this case, FL663 can be operated with best condition for LED illumination. The output voltage range is between normal output voltage (V<sub>O<sup>N</sup></sub>) and 50% of normal output voltage (V<sub>O<sup>N</sup></sub>). The other is 33 kHz. When the output voltage is dropped by decreasing the number of LEDs, the output voltage (V<sub>O</sub>) drops under 50% of normal voltage (V<sub>O<sup>N</sup></sub>). At that time, V<sub>DD</sub> drops to near UVLO protection and triggers protection. To avoid 33 kHz, V<sub>O<sup>N</sup></sub> should be designed with enough margin.
